Statistics produced for American Community Survey and included in ACS tables are survey-based estimates and are subject to error. The errors derive from research design (including instrument bias, data frame, and sampling), the survey data collection (non-response bias and response errors), and processing by the Census Bureau (data coding, compilation processes, and case weighting), as well as statistical inference error and uncertainty (which are related to sample size and variance within the measured attributes). US Census Bureau's report on 'Accuracy of the Data' can be found at http://www.census.gov/acs/www/data_documentation/documentation_main/

The Census Bureau uses a set of poverty thresholds to determine who is in poverty. These thresholds vary based on several factors and are set and applied separately to two groups: families and people living alone or with nonrelatives (unrelated individuals). For families, the thresholds vary based on family size and composition. For two-person families, the thresholds also vary based on the age of the householder. If a family's total income is less than the corresponding threshold, then that family, and every individual in it, is considered to be in poverty. Poverty thresholds for people living alone or with nonrelatives vary based on age. For a person in this category, if his or her income alone falls below the corresponding threshold, he or she is considered to be in poverty.

Statistics produced for American Community Survey and included in ACS tables are survey-based estimates and are subject to error. The errors derive from research design (including instrument bias, data frame, and sampling), the survey data collection (non-response bias and response errors), and processing by the Census Bureau (data coding, compilation processes, and case weighting), as well as statistical inference error and uncertainty (which are related to sample size and variance within the measured attributes).
